## State Space Analysis: Properties, Reachability Graph, and Coverability graph

prof.dr.ir. Wil van der Aalst

## Outline

- Motivation
- Formalization
- Basic properties
- Reachability graph
- Coverability graph

## Motivation

# Technische Universiteit <br> Eindhoven <br> University of Technology 

## Design-time analysis vs run-time analysis

## Analysis of processes

## Generic questions

## terminating

it has only finite occurrence sequences deadlock-free
each reachable marking enables a transition live

each reachable marking enables an occurrence sequence containing all transitions
bounded
each place has an upper bound that holds for all
reachable markings
1-safe
1 is a bound for each place s
reversible
m 0 is reachable from each reachable marking, i.e., the initial marking is a so-called home marking.

## Example

## Specific questions

## infinite state space state explosion problem

## Concepts

marked net

reachability graph

coverability graph

## Formalization

Note: refinement of earlier link between Petri net and transitions system (week 2/3) that is closer to standard literature.

## Basic Petri net

Definition 1 (Basic Petri net). A basic Petri net is a triple $(P, T, F)$. $P$ is a finite set of places, $T$ is a finite set of transitions $(P \cap T=\emptyset)$, and $F \subseteq(P \times T) \cup(T \times P)$ is a set of arcs (flow relation).

- $P=\{p 1, p 2\}$
- $\mathrm{T}=\{\mathrm{t} 1, \mathrm{t} 2\}$
- $\mathrm{F}=\{(\mathrm{p} 1, \mathrm{t} 1),(\mathrm{t} 1, \mathrm{p} 1)$, (t1,p2), (p1,t2), (p2,t2)\}

## Place transition net

Definition 2 (Place transition net (PT-net)). An Place transition net (or simply Petri net) is a tuple $(P, T, F, W)$, where:

- $(P, T, F)$ is a basic Petri net,
$-W \in F \rightarrow I N \backslash\{0\}$ is an (arc) weight function.
- $P=\{p 1, p 2\}$
- $\mathbf{T}=\{\mathbf{t 1 , t 2 \}}$
- $F=\{(p 1, t 1),(\mathrm{t} 1, \mathrm{p} 2)$, (p2,t2), (t2,p1)\}
- $\mathbf{W}(\mathrm{p} 1, \mathrm{t} 1)=2$,
$W(t 1, p 2)=2$,
$W(p 2, t 2)=1$, and
$\mathrm{W}(\mathrm{t} 2, \mathrm{p} 1)=1$

## Multi-sets

Definition 3 (Multi-set). Let $A$ be a set. $\mathbb{B}(A)=A \rightarrow I N$ is the set of multi-sets (bags) over $A$, i.e., $X \in \mathbb{B}(A)$ is a multi-set where for each $a \in A: X(a)$ denotes the number of times $a$ is included in the multi-set.

- $M_{0}(p 1)=2$
- $M_{0}(p 2)=3$

## Operations on multi-sets

Let $X$ and $Y$ be two multi-sets

- The sum of two multi-sets $(X+Y)$, the difference $(X-Y)$, the presence of an element in a multi-set $(x \in X)$, and the notion of sub-multi-set $(X \leq Y)$ are defined in a straightforward way.
- They can handle a mixture of sets and multi-sets.
- The operators are also robust with respect to the domains of the multi-sets, i.e., even if $X$ and $Y$ are defined on different domains, $X+Y, X-Y$, and $X \leq Y$ are defined properly by taking the union of the domains where needed.
$-|X|=\sum_{a \in A} X(a)$ is the size of some multi-set $X$ over $A$.
- $X\left(A^{\prime}\right)=\sum_{a \in A^{\prime}} X(a)$ denotes the number of elements in $X$ with a value in $A^{\prime} \subseteq A$.
- $\pi_{A^{\prime}}(X)$ is the projection of $X$ onto $A^{\prime} \subseteq A$, i.e., $\left(\pi_{A^{\prime}}(X)\right)(a)=$ $X(a)$ if $a \in A^{\prime}$ and $\left(\pi_{A^{\prime}}(X)\right)(a)=0$ if $a \notin A^{\prime}$.

## Notation

To represent a concrete multi-set we use square brackets, e.g., $[a, a, b, a, b, c]$, $\left[a^{3}, b^{2}, c\right]$, and $3[a]+2[b]+[c]$ all refer to the same multi-set with six elements: 3 's, 2 's, and one $c$. [ ] refers to the empty bag, i.e., $|[]|=0$.

- $\mathrm{M}_{0}=$
[p1,p1,p2,p2,p2] = [p12, $\mathrm{p}^{3}$ ] = 2[p1]+3[p2]
- also denoted as $(2,3)$

## Preset/postset

Definition 4 (Marking). Let $N=(P, T, F, W)$ be a Petri net. $A$ marking $M$ of $N$ is a multi-set over $P$, i.e., $M \in \mathbb{B}(P)$.

Definition 5 (Preset,postset). Let $N=(P, T, F, W)$ be a Petri net.
$-\bullet a=\left[x^{W(x, y)} \mid(x, y) \in F \wedge a=y\right]$ is the preset of $a$.
$-a \bullet=\left[y^{W(x, y)} \mid(x, y) \in F \wedge a=x\right]$ is the postset of $a$.

- Moreover, we extend the weight function for the situation that there is not an arc connecting two nodes, i.e., $W(x, y)=0$ if $(x, y) \notin F$.

## Examples

## Firing rule

Definition 6 (Firing rule). Let $N=(P, T, F, W)$ be a Petri net and $M \in \mathbb{B}(P)$ be a marking.

- A transition $t \in T$ is enabled, notation $(N, M)[t\rangle$, if and only if, $M \geq \bullet t$.
- An enabled transition $t$ can fire while changing the state to $M^{\prime}$, notation $(N, M)[t\rangle\left(N, M^{\prime}\right)$, if and only if, $M^{\prime}=(M-\bullet t)+t \bullet$.

## Notations

## Table 2 Formal Definition of a Petri Net

A Petri net is a 5-tuple, $P N=\left(P, T, F, W, M_{0}\right)$ where:
$P=\left\{p_{1}, p_{2}, \cdots, p_{m}\right\}$ is a finite set of places, Murata
$T=\left\{t_{1}, t_{2}, \cdots, t_{n}\right\}$ is a finite set of transitions,
$F \subseteq(P \times T) \cup(T \times P)$ is a set of arcs (flow relation),

$W: F \rightarrow\{1,2,3, \cdots\}$ is a weight function,
$M_{0}: P \rightarrow\{0,1,2,3, \cdots\}$ is the initial marking,
$P \cap T=\varnothing$ and $P \cup T \neq \varnothing$.
A Petri net structure $N=(P, T, F, W)$ without any specific initial marking is denoted by $N$.
A Petri net with the given initial marking is denoted by $\left(N, M_{0}\right)$.

A net $N$ is constituted by

## Desel/Reisig

- a set $S$ of places,
- a set $T$ of transitions such that $S \cap T=\emptyset$, and
- a set $F$ of directed arcs (flow relation), $F \subseteq(S \cup T) \times(S \cup T)$, satisfying

$$
F \cap(S \times S)=F \cap(T \times T)=\emptyset
$$

## Notations: Firing rule

The behavior of many systems can be described in terms of system states and their changes. In order to simulate the dynamic behavior of a system, a state or marking in a Petri nets is changed according to the following transition (firing) rule:

1) A transition $t$ is said to be enabled if each input place $p$ of $t$ is marked with at least $w(p, t)$ tokens, where $w(p$, $t$ ) is the weight of the arc from $p$ to $t$.
2) An enabled transition may or may not fire (depending on whether or not the event actually takes place).
3) A firing of an enabled transition $t$ removes $w(p, t)$ tokens from each input place $p$ of $t$, and adds $w(t, p)$ tokens to each output place $p$ of $t$, where $w(t, p)$ is the weight of the arc from $t$ to $p$.

Murata

$$
\begin{aligned}
& \text { A marking of a net } N \text { is a mapping } m: S_{N} \rightarrow \mathbb{N} \text { where } \mathbb{N}=\{0,1,2, \ldots\} \text {. A } \\

\end{aligned}
$$

## Basic Properties

## Basic properties of a marked Petri net

Definition 9 (Basic properties). Let $N=(P, T, F, W)$ be a Petri net and $M \in \mathbb{B}(P)$ be a marking.
$-(N, M)$ is terminating if and only if there is a $k \in \mathbb{N}$ such that $|\sigma| \leq k$ for any firing sequence $\sigma$ (i.e., $(N, M)[\sigma\rangle)$.
$-(N, M)$ is deadlock-free if and only if for any $M^{\prime} \in R(N, M)$ there exists a transition $t$ such that $\left(N, M^{\prime}\right)[t\rangle$.
$-(N, M)$ is live if and only if for any $t \in T$ and any $M^{\prime} \in R(N, M)$ there exists a $M^{\prime \prime} \in R\left(N, M^{\prime}\right)$ such that $\left(N, M^{\prime \prime}\right)[t\rangle$.
$-(N, M)$ is bounded if and only if there is a $k \in I N$ such that for any $M^{\prime} \in R(N, M)$ and any $p \in P: M^{\prime}(p) \leq k$.
$-(N, M)$ is safe if and only if for any $M^{\prime} \in R(N, M)$ and any $p \in P: M^{\prime}(p) \leq 1$.
$-(N, M)$ is reversible if and only if for any $M^{\prime} \in R(N, M): M \in$ $R\left(N, M^{\prime}\right)$.

## Terminating

$(N, M)$ is terminating if and only if there is a $k \in \mathbb{N}$ such that $|\sigma| \leq k$ for any firing sequence $\sigma$ (i.e., $(N, M)[\sigma\rangle)$.

## Deadlock-free

$(N, M)$ is deadlock-free if and only if for any $M^{\prime} \in R(N, M)$ there exists a transition $t$ such that $\left(N, M^{\prime}\right)[t\rangle$.

## Liveness

Transition $t \in T$ is live in $(N, M)$ if and only if for any $M^{\prime} \in$ $R(N, M)$ there exists a $M^{\prime \prime} \in R\left(N, M^{\prime}\right)$ such that $\left(N, M^{\prime \prime}\right)[t\rangle$.

$(N, M)$ is live is all of its transitions are live.

## Basic idea of liveness

## Boundedness

Place $p \in P$ is $k$-bounded in $(N, M)$ if and only if for any $M^{\prime} \in$ $R(N, M): M^{\prime}(p) \leq k$.

Place $p \in P$ is bounded in $(N, M)$ if and only if there is a $k \in \mathbb{N}$ such that $p$ is $k$-bounded.
$(N, M)$ is bounded if and only if all of its places are bounded.

## Safeness

Place $p \in P$ is safe in $(N, M)$ if and only if $p$ is 1-bounded.
$(N, M)$ is safe if and only if all of its places are safe.

TU/e=

## Reversible/home marking.

$(N, M)$ is reversible if and only if for any $M^{\prime} \in R(N, M): M \in$ $R\left(N, M^{\prime}\right)$.

Marking $M^{\prime}$ is a home marking in $(N, M)$ if it is reachable from any reachable marking, i.e., for any $M^{\prime \prime} \in R(N, M): M^{\prime} \in R\left(N, M^{\prime \prime}\right)$.
( $N, M$ ) is reversible if and only if $M$ is a home marking.

## Reachability Graph

## Technische Universiteit <br> Eindhoven <br> University of Technology

## Definition

Definition 10 (Reachability graph). Let $N=(P, T, F, W)$ be a Petri net and $M \in \mathbb{B}(P)$ be a marking. The reachability graph of $(N, M)$ is the graph $(V, E)$ with as vertices $V=R(N, M)$ the set of all reachable markings and as edges $E=\left\{\left(M^{\prime}, t, M^{\prime \prime}\right) \in V \times T \times\right.$ $V \mid\left(\left(N, M^{\prime}\right)[t\rangle\left(N, M^{\prime \prime}\right)\right\}$ the set of all possible state changes. Note that $\left(M^{\prime}, t, M^{\prime \prime}\right) \in E$ denotes that $M^{\prime \prime}$ is reachable from $M^{\prime}$ by firing $t$.

TU/e

## Reachability graph algorithm

1) Label the initial marking $M_{0}$ as the root and tag it "new".
2) While "new" markings exists, do the following:
a) Select a new marking $M$.
b) If no transitions are enabled at $M, \operatorname{tag} M$ "dead-end".
c) While there exist enabled transitions at $M$, do the following for each enabled transition $t$ at $M$ :
i. Obtain the marking $M^{\prime}$ that results from firing $t$ at $M$.
ii. If $M^{\prime}$ does not appear in the graph, add $M^{\prime}$ and tag it "new".
iii. Draw an arc with label $t$ from $M$ to $M^{\prime}$ (if not already present).
3) Output the graph.

## Example

## [p1,free,p4]

Step 1: Label the initial marking MO as the root and tag it "new" (indicated by green color).

## Example (continued)

[p1,free, p4]

[p1,free,p4] [p2,free,p4]

[p1,free,p5]

## Example (continued)

[p1,free,p5]

[p1,free,p5] [p2,free,p5]

## Example (continued)

## Example (continued)

## Example (continued)

## Example (continued)

## Example (continued)

## Example (continued)

## Example (complete)

- The marked Petri net is:
$\checkmark$ deadlock free
$\checkmark$ live
$\checkmark$ bounded
$\checkmark$ safe
$\checkmark$ reversible
$\checkmark$ all markings are home markings

## Coverability Graph

## Problem

ps. $(n, m)$ is a shorthand for $\left[p 1^{n}, p 2^{m}\right]$

## Coverability tree algorithm

1) Label the initial marking $M_{0}$ as the root and tag it "new".
2) While "new" markings exists, do the following:
a) Select a new marking $M$ and remove the "new" tag.
b) If $M$ is identical to a marking on the path from the root to $M$, then tag $M$ "old" and go to another new marking.
c) If no transitions are enabled at $M$, $\operatorname{tag} M$ "dead-end".
d) While there exist enabled transitions at $M$, do the following for each enabled transition $t$ at $M$ :
i. Obtain the marking $M^{\prime}$ that results from firing $t$ at $M$.
ii. If, on the path from the root to $M$, there exists a marking $M$ " such that $M^{\prime}(p) \geq M^{\prime \prime}(p)$ for each $p$ and $M^{\prime} \neq M^{\prime \prime}$ (i.e., $M^{\prime \prime}$ is coverable), then replace $M^{\prime}(p)$ by $\omega$ for each $p$ such that $M^{\prime}(p)>M^{\prime \prime}(p)$.
iii. Introduce $M^{\prime}$ as a node, draw an arc with label $t$ from $M$ to $M^{\prime}$, and tag $M^{\prime}$ "new".
3) Output the tree.

## Example

Step 1: Label the initial marking $M_{0}$ as the root and tag it "new" (indicated by green color).

## Example (continued)

Step 2: While "new" markings exists, do the following:

- $\quad$ Select a new marking $M$ and remove the "new" tag.
- If $M$ is identical to a marking on the path from the root to $M$,
 then $\operatorname{tag} M$ "old" and go to another new marking.
- If no transitions are enabled at $M$, tag $M$ "dead-end".
- While there exist enabled transitions at $M$, do the following for each enabled transition $t$ at $M$ :
- Obtain the marking $M^{\prime}$ that results from firing $t$ at $M$.
- If, on the path from the root to $M$, there exists a marking $M^{\prime \prime}$ such that $M^{\prime}(p) \geq M^{\prime \prime}(p)$ for each $p$ and $M^{\prime} \neq M^{\prime \prime}$ (i.e., $M^{\prime \prime}$ is coverable), then replace $M^{\prime}(p)$ by $\omega$ for each $p$ such that $M^{\prime}(p)>M^{\prime \prime}(p)$.
- Introduce $M^{\prime}$ as a node, draw an arc with label $t$ from $M$ to $M^{\prime}$, and tag $M^{\prime}$ "new"
[p1]

## Example (continued)

Step 2: While "new" markings exists, do the following:

- Select a new marking $M$ and remove the "new" tag.
- If $M$ is identical to a marking on the path from the root to $M$,

## Example (continued)

Step 2: While "new" markings exists, do the following:

- Select a new marking $M$ and remove the "new" tag.
- If $M$ is identical to a marking on the path from the root to
 $M$, then $\operatorname{tag} M$ "old" and go to another new marking.
- If no transitions are enabled at $M$, tag $M$ "dead-end".
- While there exist enabled transitions at $M$, do the following for each enabled transition $t$ at $M$ :
- Obtain the marking $M^{\prime}$ that results from firing $t$ at $M$.
- If, on the path from the root to $M$, there exists a marking $M^{\prime \prime}$ such that $M^{\prime}(p) \geq M^{\prime \prime}(p)$ for each $p$ and $M^{\prime} \neq M^{\prime \prime}$ (i.e., $M^{\prime \prime}$ is coverable), then replace $M^{\prime}(p)$ by $\omega$ for each $p$ such that $M^{\prime}(p)>M^{\prime \prime}(p)$.
- Introduce $M^{\prime}$ as a node, draw an arc with label $t$ from $M$ to $M^{\prime}$, and tag $M^{\prime}$ "new"

## Example (complete)

Step 3: Output the tree.

Coverability graph:

## Example (continued)

## Step 3: Output the tree.

## Example (complete)

## Coverability graph

- Take the coverability tree and simply merge nodes with identical labels

## Another example

## w-markings

Definition 11 ( $\omega$-marking). Let $N=(P, T, F, W)$ be a Petri net with initial marking $M^{\prime}$.

An $\omega$-marking $M$ of $N$ is an extended multi-set over $P$, i.e., $M \in$ $A \rightarrow(\mathbb{N} \cup\{\omega\})$.

If $M(p)=\omega$, then place $p \in P$ is said to be unbounded in $M$.
If $M(p) \neq \omega$ for all $p \in P$, then $M$ is said to be $\omega$-free.
$M$ is a reachable $\omega$-marking of $\left(N, M^{\prime}\right)$ if and only if it appears in the coverability graph of $\left(N, M^{\prime}\right)$.

TU/e $=$

## Properties

- The coverability tree/graph is always finite.
- The marked Petri net is bounded if and only if the corresponding coverability tree/graph contains only $\omega$-free markings.
- The coverability tree/graph gives an over-approximation.
- Different Petri nets may have the same coverability tree/graph.

## Basic relation between reachable markings and coverability tree/graph

Theorem 1 (Relation). Let $N=(P, T, F, W)$ be a Petri net and $M \in \mathbb{B}(P)$ be a marking. Let $M^{\prime}$ be an $\omega$-marking appearing in the coverability graph of $(N, M)$ and $n \in \mathbb{N}$ an arbitrary number.

There exists an $M^{\prime \prime} \in R(N, M)$ such that for all $p \in P$ :

- If $M^{\prime}(p) \neq \omega$, then $M^{\prime \prime}(p)=M^{\prime}(p)$.
- If $M^{\prime}(p)=\omega$, then $M^{\prime \prime}(p) \geq n$.

Let $n=180$. There is a reachable marking with 0 tokens in p1 and at least 180 tokens in p2.

## Example (readers and writers)

## Initial part

TU/e

## Coverability tree

TU/e

## Coverability graph

## Coverability graph (vector notation)

## Analysis results

- p1, p2, p4, p5 are safe
- p3 is unbounded
- [p2,p5] is reachable

- [p1,p2] is not reachable
- [p1,p3 ${ }^{180}, \mathrm{p} 5$ ] is coverable

## Additional properties

- A transition $t$ is dead if and only if if does not appear in the coverability graph.
- The coverability graph and reachability graph are identical if the marked Petri net is bounded (i.e., only $\omega$-free markings).
- The marked Petri net is safe if only 0's and 1's appear in nodes.
- Any firing sequence of the marked Petri net can be matched by a "walk" through the coverability graph.
- The reverse is not true!!!!

## Limitation: Loss of information

Two nets with the same coverability graph!

\{[p1],[p1,p2¹],
[p1,p2²], [p1,p23], [p1,p24], ...\}

\{[p1],[p1,p2³], [p1,p26], [p1,p29], [p1,p212], ...\}

## State-explosion problem (1)

## State-explosion problem (2)

## place $s$ is

 $2^{n}$ bounded

Each round the number of tokens in s can be doubled.

## Variants

- Construct the coverability graph on the fly (i.e., do not first construct the coverability tree): the graph may become smaller but process is typically non-deterministic.
- Several approaches have been proposed to construct "minimal" coverability graphs/sets (see "Alain Finkel: The Minimal Coverability Graph for Petri Nets. Applications and Theory of Petri Nets 1991: 210-243", and "Gilles Geeraerts, Jean-François Raskin, Laurent Van Begin: On the Efficient Computation of the Minimal Coverability Set for Petri Nets. ATVA 2007: 98-113")

## Conclusion

## The coverability graph is finite but ...

- some information gets lost in case of unbounded behavior, and
- it may be huge and impossible to construct.

Next: structural methods like invariants, siphons, traps, etc.

## After this lecture you should be able to:

- Understand the formalizations, i.e., (P,T,F,W), M, (N,M)[t>(N,M'), etc.
- Determine whether a concrete marked net is terminating, deadlockfree, live, bounded, safe, and/or reversible, whether a transition is live and/or dead, whether a place is k-bounded, etc.
- Construct a Petri net that has a set of desirable properties, e.g., a net that is live and bounded but not reversible.
- Construct the reachability graph of a marked net.
- Construct the coverability tree of a marked net.
- Construct the coverability graph of a marked net.
- Tell which properties can(not) be derived from the coverability tree/graph.
- Understand the limitations of the coverability tree/graph (loss of information, inability to decide liveness, etc.).
- Derive conclusions from a concrete coverability tree/graph.

## Appendix: Formalization of Coverability Graph based on Desel \& Reisig

## Coverability tree \& graph

- Idea: cut-off unbounded behavior using omega ( $\omega$ ) markings

Formally, an $\omega$-marking of a net $N$ is a mapping $\bar{m}: S_{N} \rightarrow \mathbb{N} \cup\{\omega\}$ where $\omega \notin \mathbb{N}$. Clearly, every (conventional) marking can be viewed as a particular $\omega$-marking without $\omega$-entries.

$$
(1,0, \omega, 1, \omega, 1,2,0)
$$

$\omega$-markings are interpreted as follows: If a marking $m^{\prime}$ is reachable from a marking $m$ and satisfies $m^{\prime}(s) \geq m(s)$ for each place $s$, the occurrence sequence leading from $m$ to $m^{\prime}$ can be iterated arbitrarily often (Proposition 5). If moreover $m^{\prime}\left(s_{0}\right)>m\left(s_{0}\right)$ for some place $s_{0}$ then the number of tokens on $s_{0}$ increases with each iteration of the occurrence sequence. This increasing sequence of markings is now replaced by one $\omega$-marking $\overline{m^{\prime}}$ with $\overline{m^{\prime}}\left(s_{0}\right)=\omega$, denoting that, for each $b \in \mathbb{N}$, there is a reachable marking that coincides with $m^{\prime}$ for all places except $s_{0}$ and assigns at least $b$ tokens to $s_{0}$. More generally, several places may map to $\omega$, representing simultaneous growth of the token count on these places.

## Trivial example

## Extended example

## Approach

1. Define omega ( $\omega$ ) occurrence sequences.
2. Show that these are finite.
3. Construct coverability tree
4. Construct coverability graph

## Example of a $\omega$-occurrence sequence

- $\omega$-occurrence sequence: t1 t1
- $(1,0)$-t1-> $(1, \omega)$-t1-> $(1, \omega)$

marked net

A (finite or infinite) sequence of transitions $t_{1} t_{2} t_{3} \ldots$ is an $\omega$-occurrence sequence of a marked net with initial marking $m_{0}$ if there exist $\omega$-markings $\bar{m}_{0}, \bar{m}_{1}, \bar{m}_{2}, \ldots$ such that $m_{0}$ and $\bar{m}_{0}$ coincide for all places and, for each index $i$ occurring in the sequence $t_{1} t_{2} t_{3} \ldots$ the following conditions hold:
(1) For each place $s$ in ${ }^{\bullet} t_{i}$, either $\bar{m}_{i-1}(s)>0$ or $\bar{m}_{i-1}(s)=\omega$ (the enabling condition).
(2) For each place $s$ satisfying $\bar{m}_{i}(s) \neq \omega$,

$$
\bar{m}_{i}(s)=\bar{m}_{i-1}(s)-\left|F_{N} \cap\left\{\left(s, t_{i}\right)\right\}\right|+\left|F_{N} \cap\left\{\left(t_{i}, s\right)\right\}\right|
$$

(the conventional marking transformation).
(3) A place $s$ satisfies $\bar{m}_{i}(s)=\omega$ if and only if

- either $\bar{m}_{i-1}(s)=\omega$
(places marked by $\omega$ remain marked by $\omega$ ),
- or $\bar{m}_{i-1}(s) \neq \omega$ and there exists an index $j, j<i$, such that $\bar{m}_{j}(s) \neq \omega$ and $\bar{m}_{j}(s)<\bar{m}_{i-1}(s)-\left|F_{N} \cap\left\{\left(s, t_{i}\right)\right\}\right|+\left|F_{N} \cap\left\{\left(t_{i}, s\right)\right\}\right|$ and $\bar{m}_{j}\left(s^{\prime}\right) \leq \bar{m}_{i-1}\left(s^{\prime}\right)-\left|F_{N} \cap\left\{\left(s^{\prime}, t_{i}\right)\right\}\right|+\left|F_{N} \cap\left\{\left(t_{i}, s^{\prime}\right)\right\}\right|$ for each place $s^{\prime}$ satisfying $\bar{m}_{j}\left(s^{\prime}\right) \neq \omega$ and $\bar{m}_{i-1}\left(s^{i}\right) \neq \omega$ (places with increasing token count are marked by $\omega$ ).
(4) If $i>1$ then $\bar{m}_{i-1} \notin\left\{\bar{m}_{0}, \ldots, \bar{m}_{i-2}\right\}$
(after reaching an $\omega$-marking the second time, the sequence stops).
We call an $\omega$-marking $\bar{m}$ reachable in a marked net if some $\omega$-occurrence sequence leads to $\bar{m}$.

## (1) Transitions need to be enabled

marked net

Only t1 is enabled in $(1,0)$, not $t 2$.
$\omega$-occurrence sequences
(1) For each place $s$ in ${ }^{\bullet} t_{i}$, either $\bar{m}_{i-1}(s)>0$ or $\bar{m}_{i-1}(s)=\omega$ (the enabling condition).

## (2) For non-w place markings: business as usual

(2) For each place $s$ satisfying $\bar{m}_{i}(s) \neq \omega$,

$$
\bar{m}_{i}(s)=\bar{m}_{i-1}(s)-\left|F_{N} \cap\left\{\left(s, t_{i}\right)\right\}\right|+\left|F_{N} \cap\left\{\left(t_{i}, s\right)\right\}\right|
$$

(the conventional marking transformation).

## (3) Introducing omegas

(3) A place $s$ satisfies $\bar{m}_{i}(s)=\omega$ if and only if

- either $\bar{m}_{i-1}(s)=\omega$
(places marked by $\omega$ remain marked by $\omega$ ),
- or $\bar{m}_{i-1}(s) \neq \omega$ and there exists an index $j, j<i$, such that $\bar{m}_{j}(s) \neq \omega$ and $\bar{m}_{j}(s)<\bar{m}_{i-1}(s)-\left|F_{N} \cap\left\{\left(s, t_{i}\right)\right\}\right|+\left|F_{N} \cap\left\{\left(t_{i}, s\right)\right\}\right|$ and $\bar{m}_{j}\left(s^{\prime}\right) \leq \bar{m}_{i-1}\left(s^{\prime}\right)-\left|F_{N} \cap\left\{\left(s^{\prime}, t_{i}\right)\right\}\right|+\left|F_{N} \cap\left\{\left(t_{i}, s^{\prime}\right)\right\}\right|$ for each place $s^{\prime}$ satisfying $\bar{m}_{j}\left(s^{\prime}\right) \neq \omega$ and $\bar{m}_{i-1}\left(s^{\prime}\right) \neq \omega$ (places with increasing token count are marked by $\omega$ ).

## (4) Stop after second identical marking

marked net

Marking
$(0, \omega)$ is dead while $(1, \omega)$ markings are not
continued after second occurrence.
(4) If $i>1$ then $\bar{m}_{i-1} \notin\left\{\bar{m}_{0}, \ldots, \bar{m}_{i-2}\right\}$
(after reaching an $\omega$-marking the second time, the sequence stops).

## Finite?

- How long can a $\omega$-occurrence sequence be?
- How many w-occurrence sequences are there?
- Is the coverability tree/graph finite?

## Dickson's Lemma (1874-1954)

Lemma 17. Let $S$ be a finite set and let $\varphi_{1} \varphi_{2} \varphi_{3} \ldots$ be an infinite sequence of mappings from $S$ to $\mathbb{N} \cup\{\omega\}$. There exists an infinite sequence of indices $i_{1} i_{2} i_{3} \ldots$ which is strongly monotonic (i.e., $i_{1}<i_{2}<i_{3}<\cdots$ ) such that, for each $s$ in $S$,

$$
\varphi_{i_{1}}(s) \leq \varphi_{i_{2}}(s) \leq \varphi_{i_{3}}(s) \leq \cdots
$$

| 1 | $\mathbb{1}$ | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 1 | $\mathbb{1}$ | $\infty$ | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | $\mathbb{1}$ | $\mathbb{1}$ | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | $\mathbb{1}$ | 11 | 0 |
| 0 | $\oplus$ | $\mathbb{1}$ | 1 | 1 | 0 | 0 | 1 | 1 | 1 | 0 | $\varnothing$ | 11 | 1 |
| 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 2 | 2 | 2 | $\mathbb{T U} / \mathrm{e}$ | 2 | 3 |

Proof. We prove the following stronger proposition: For each subset $S^{\prime}$ of $S$, there exists an infinite strongly monotonic sequence of indices $i_{1}, i_{2}, i_{3}, \ldots$ such that, for each $s$ in $S^{\prime}, \varphi_{i_{1}}(s) \leq \varphi_{i_{2}}(s) \leq \varphi_{i_{3}}(s) \leq \cdots$. We proceed by induction on the number of elements in $S^{\prime}$.
Base. If $S^{\prime}=\emptyset$ then nothing has to be shown.
Step. Assume $S^{\prime} \neq \emptyset$ and let $s \in S^{\prime}$. By the induction hypothesis, there exists an infinite strongly monotonic sequence $i_{1}, i_{2}, i_{3}, \ldots$ such that, for each $s^{\prime}$ in $S^{\prime} \backslash\{s\}$,

$$
\varphi_{i_{1}}\left(s^{\prime}\right) \leq \varphi_{i_{2}}\left(s^{\prime}\right) \leq \varphi_{i_{3}}\left(s^{\prime}\right) \leq \cdots
$$

Now we restrict the sequence $i_{1}, i_{2}, i_{3}, \ldots$ to indices $i_{k}$ satisfying

$$
\varphi_{i_{k}}(s) \leq \varphi_{i_{k+1}}(s), \quad \varphi_{i_{k}}(s) \leq \varphi_{i_{k+2}}(s), \quad \varphi_{i_{k}}(s) \leq \varphi_{i_{k+3}}(s) \ldots
$$

Clearly, the obtained sequence $i_{k_{1}}, i_{k_{2}}, i_{k_{3}}, \ldots$ satisfies the required property

$$
\varphi_{i_{k_{1}}}(s) \leq \varphi_{i_{k_{2}}}(s) \leq \varphi_{i_{k_{3}}}(s) \leq \cdots
$$

for each place $s$ in $S^{\prime}$. This sequence is infinite because, for each index $i_{k}$, every index $i_{l}$ in $\left\{i_{k+1}, i_{k+2}, i_{k+3} \ldots\right\}$ satisfying

$$
\varphi_{i_{1}}(s) \leq \varphi_{i_{k+1}}(s), \varphi_{i_{k+2}}(s), \varphi_{i_{k+3}}(s) \ldots
$$

belongs to the sequence, too. Such an index $i_{l}$ always exists because every nonempty subset of $\mathbb{N} \cup\{\omega\}$ has a minimal element.

Theorem 18. Every $\omega$-occurrence sequence of a finite marked net is finite.
Proof. By contraposition, assume a finite marked net that has an infinite $\omega$ occurrence sequence $t_{1} t_{2} t_{3} \ldots$,

$$
\bar{m}_{1} \xrightarrow{t_{1}} \bar{m}_{2} \xrightarrow{t_{2}} \bar{m}_{3} \xrightarrow{t_{3}} \cdots .
$$

By Dickson's Lemma (Lemma 17), there exists an infinite strongly monotonic sequence of indices $i_{1}, i_{2}, i_{3} \ldots$ such that, for each place $s$,

$$
\bar{m}_{i_{1}}(s) \leq \bar{m}_{i_{2}}(s) \leq \bar{m}_{i_{3}}(s) \leq \cdots
$$

Let $i$ and $j$ be two subsequent indices of the sequence $i_{1}, i_{2}, i_{3} \ldots$. By the definition of $\omega$-occurrence sequences (4) no $\omega$-marking appears twice in an infinite $\omega$-occurrence sequence. Hence $\bar{m}_{i}(s) \neq \bar{m}_{j}(s)$ for at least one place $s$. By the definition of $\omega$-occurrence sequences (3), $\bar{m}_{i}(s) \neq \omega$ and $\bar{m}_{j}(s)=\omega$. Again by (3), no place $s$ satisfies $\bar{m}_{i}(s)=\omega$ and $\bar{m}_{j}(s) \neq \omega$. Hence $\bar{m}_{j}$ has more places with $\omega$-entries than $\bar{m}_{i}$. Therefore, the set of places with $\omega$-entries increases infinitely, contradicting the finiteness of the set of all places of the net.

## Coverability tree

Diagrams are a bit misleading: vertices labeled with a $\omega$-marking are really sequences, e.g., initial node is $\varepsilon$ rather than (1,0).

$\omega$-occurrence sequences
coverability tree

Formally, the coverability tree of a marked net is defined as a directed graph with a distinguished initial vertex and edges labeled by transitions:

- the vertices are the finite $\omega$-occurrence sequences,
- a distinguished initial vertex is given by the empty sequence $\varepsilon$ (which by definition is an $\omega$-occurrence sequence),
- labeled edges are all triples $(\sigma, t, \sigma t)$ such that $\sigma$ as well as $\sigma t$ are $\omega$ occurrence sequences.

## Finiteness

Theorem 19. The coverability tree of a finite marked net is finite. ${ }^{8}$
Proof. By contraposition, assume a finite marked net with an infinite coverability tree. Each vertex $\sigma$ of the coverability tree has only finitely many immediate successors, one for each transition enabled by the $\omega$-marking reached by $\sigma$. Hence every vertex $\sigma$ with infinitely many successors has at least one immediate successor which also has infinitely many successors. By assumption, the initial vertex $\varepsilon$ has infinitely many successors. Hence, starting with $\varepsilon$, we can construct an infinite directed path of the tree. The concatenation of the labels of the edges of this path yields an infinite $\omega$-occurrence sequence - contradicting Theorem 18.

Corollary 20. A finite marked net has finitely many reachable $\omega$-markings.

## Example

Fig. 12. An unbounded marked Petri net

## Marking graph <br> (i.e., reachability graph)

## Coverability tree

find the error (also in paper)...

## Relation $\omega$-markings and normal markings

Theorem 21. Let $\bar{m}$ be a reachable $\omega$-marking of a finite marked net. For each $b$ in $I N$, there is a reachable marking $m$ such that every place $s$ satisfies:

- if $\bar{m}(s) \neq \omega$ then $m(s)=\bar{m}(s)$,
- if $\bar{m}(s)=\omega$ then $m(s) \geq b$.

Let $b=180$. There is $a$ marking reachable with 0 tokens in p1 and at least 180 tokens in p2.

## Boundedness = "all $\omega$-markings are $\omega$ free"

Theorem 23. A place $s$ of a marked net is not bounded if and only if some reachable $\omega$-marking $\bar{m}$ satisfies $\bar{m}(s)=\omega$ (i.e., some vertex of the coverability tree represents the $\omega$-marking $\bar{m}$ ).

Proof.
$(\Longleftarrow)$ follows immediately from Theorem 21.
$(\Longrightarrow)$ Since there are only finitely many reachable $\omega$-markings by Theorem 19 there is a number $b \in \mathbb{N}$ such that each reachable $\omega$-marking $\bar{m}$ satisfies either $\bar{m}(s)=\omega$ or $\bar{m}(s)<b$. Since $s$ is not bounded, some reachable marking $m$ satisfies $m(s) \geq b$. Since $m(s)$ does not coincide with $\bar{m}(s)$ for any reachable $\omega$-marking $\bar{m}(s)$, there exists some reachable $\omega$-marking $\bar{m}$ satisfying $\bar{m}(s)=\omega$ by Theorem 22.

## b-boundedness

Corollary 24. A place s of a marked net is b-bounded if and only if each reachable $\omega$-marking $\bar{m}$ satisfies $\bar{m}(s) \neq \omega$ and $\bar{m}(s) \leq b$.

$$
\begin{aligned}
& \text { p1 is 1-boundned (safe) } \\
& \text { p2 is unbounded }
\end{aligned}
$$

## Dead transitions do not appear in cov. tree

Theorem 25. A transition $t$ of a marked net is dead if and only if $t$ does not occur in any $\omega$-occurrence sequence (i.e., some arc of the coverability tree is labeled by $t$ ).

Proof.
$(\Longleftrightarrow)$ Assume some reachable marking $m$ enables $t$. By Theorem 22, a corresponding reachable $\omega$-marking $\bar{m}$ satisfies $\bar{m}(s) \neq 0$ for each place $s$ in ${ }^{\bullet} t$. Hence, this $\omega$-marking enables $t$, too.
$(\Longrightarrow$ ) Assume some reachable $\omega$-marking $\bar{m}$ enables $t$. By Theorem 21, there is a corresponding reachable marking $m$ that marks all places satisfying $\bar{m}=\omega$ at least once. This marking $m$ enables $t$, too.

## Coverability graph (versus cov. tree)

The coverability graph of a marked net is defined as an arc-labeled directed graph with a distinguished initial vertex and edges labeled by transitions:

- the vertices are the reachable $\omega$-markings,
- the distinguished initial vertex is given by the $\omega$-marking that coincides with the initial marking for each place,
- labeled edges are given by all triples ( $\bar{m}, t, \bar{m}^{\prime}$ ) such that $\bar{m}$ and $\bar{m}^{\prime}$ are reachable $\omega$-markings satisfying $\bar{m} \xrightarrow{t} \bar{m}^{\prime}$.

## Boundedness implies equivalence

Theorem 27. The coverability graph and the marking graph of a bounded marked net are identical (up to different co-domains of markings and $\omega$-markings).

Proof. The result follows immediately from Corollary 26 and the definition of $\omega$-occurrence sequences.

## Appendix: Examples taken from Murata

Where innovation starts tree

The coverability tree for a Petri net $\left(N, M_{0}\right)$ is constructed by the following algorithm.

Step 1) Label the initial marking $M_{0}$ as the root and tag it "new."
Step 2) While "new" markings exist, do the following:
Step 2.1) Select a new marking $M$.
Step 2.2) If $M$ is identical to a marking on the path from the root to $M$, then $\operatorname{tag} M$ "old" and go to another new marking.
Step 2.3) If no transitions are enabled at $M, \operatorname{tag} M^{\prime \prime}$ deadend."
Step 2.4) While there exist enabled transitions at $M$, do the following for each enabled transition $t$ at M:
Step 2.4.1) Obtain the marking $M^{\prime}$ that results from firing $t$ at $M$.
Step 2.4.2) On the path from the root to $M$ if there exists a marking $M^{\prime \prime}$ such that $M^{\prime}(p) \geq$ $M^{\prime \prime}(p)$ for each place $p$ and $M^{\prime} \neq M^{\prime \prime}$, i.e., $M^{\prime \prime}$ is coverable, then replace $M^{\prime}(p)$ by $\omega$ for each $p$ such that $M^{\prime}(p)>M^{\prime \prime}(p)$.
Step 2.4.3) Introduce $M^{\prime}$ as a node, draw an arc with label $t$ from $M$ to $M^{\prime}$, and tag $M^{\prime \prime}$ new."

## Example

## Properties

Some of the properties that can be studied by using the coverability tree $T$ for a Petri $\operatorname{Net}\left(\mathbb{N}, M_{0}\right)$ are the foltowing:

1) A net ( $N, M_{0}$ ) is bounded and thus $R\left(M_{0}\right)$ is finite iff (if and only if) $\omega$ does not appear in any node labels in $T$.
2) A net $\left(N, M_{0}\right)$ is safe iff only 0 's and 1 's appear in node labels in $T$.
3) A transition $t$ is dead iff it does not appear as an arc label in $T$.
4) If $M$ is reachable from $M_{0}$, then there exists a node labeled $M^{\prime}$ such that $M \leq M^{\prime}$.

## Coverability graph
